Neighborhood-aware address translation for irregular GPU applications

could bottleneck on virtual to physical address translations. In a single instruction multiple thread (SIMT) execution, many concurrent memory accesses, all of which require address translation before accesses can complete. Unfortunately, many of these address translation requests often miss in the TLB, generating many concurrent page table walks. In this work, we investigate how to reduce address translation overheads for such applications. We observe that many of these concurrent page table walks, while irregular from the perspective of a single CPU viewpoint, still fall on neighboring virtual page addresses. The address mappings for these neighboring pages are typically stored in the same 86-byte cache line. Since caches are the smallest granularity of memory access, the page table walker implicitly reads address mappings of many neighboring pages during the page walk of a single virtual address. However, in the conventional hardware, mappings not associated with the original request are simply discarded. In this work, we propose mechanisms to coalesce the address translation needs of all pending page table walks in the same neighborhood that happens to have their address mappings fall on the same cache line. This is almost free as the page table walker already reads a full cache line containing address mappings of all pages in the same neighborhood. We find this simple scheme can reduce the number of accesses to the memory page table by 59% on average. This speeds up a set of CPU workloads by an average of 10%.

Bio: Seunghee Shin received his Ph.D. degree from Electrical and Computer Engineering department at North Carolina State University, Raleigh, NC. His primary research interests lie in computer architecture and systems. Specifically, he has high interests in investigating the impact of emerging technologies on memory systems in modern processors. He

M.S. degree in Computer Science from Northeastern University, MA, where he studied computer networks.
